Course: Image Processing and Computer Vision (IPCV)

## Abstract

This report presents a complete Real-Time Object Detection and Counting System developed using YOLOv8 (Nano variant) from the Ultralytics framework. The system is capable of detecting and counting 80 object categories from the COCO dataset in both images and video streams. The pipeline follows the standard six-step mini project structure: data collection, preprocessing, feature extraction, algorithm implementation, evaluation, and reporting.

Three mandatory preprocessing filters — Resize, Gaussian Denoising, and CLAHE contrast enhancement — are applied to each input frame before inference. The YOLOv8n backbone automatically extracts multi-scale feature representations through its CSPDarknet53 architecture, eliminating the need for manual feature engineering. Detection results are visualised with colour-coded bounding boxes, class labels, confidence scores, and a per-frame object count panel.

The YOLOv8n model achieves a published mAP@0.5 of 52.9% and m re AP@0.5:0.95 of 37.3% on the COCO val2017 benchmark, with an inference speed of approximately 0.99ms per frame on GPU. The system was developed and tested on Google Colab using a Tesla T4 GPU. Applications include autonomous vehicles, retail analytics, security surveillance, and smart city monitoring.

# 1. Introduction

## 1.1 Background and Motivation

Object detection is one of the most fundamental problems in computer vision, with applications spanning autonomous driving, medical imaging, retail analytics, and security surveillance. Unlike image classification — which assigns a single label to an entire image — object detection simultaneously localises and classifies multiple objects within an image, providing both the class label and the precise bounding box coordinates for each detected instance.

The ability to detect objects in real time has become increasingly important as video surveillance systems, autonomous vehicles, and smart manufacturing systems demand low-latency, high-accuracy visual understanding. YOLO (You Only Look Once) represents a paradigm shift in real-time object detection by processing the entire image in a single forward pass through the neural network, achieving state-of-the-art accuracy at speeds exceeding 30 frames per second.

## 1.2 Problem Statement

This project addresses the problem of real-time multi-class object detection and counting from arbitrary input images and video files. Given an input image or video stream, the system must: (1) detect the location of all objects belonging to the 80 COCO categories, (2) classify each detected region with a confidence score, (3) count the number of instances of each class, and (4) overlay this information on the output in a visually informative manner.

## 1.3 Objectives

- Implement a complete object detection pipeline using YOLOv8n pre-trained on the COCO dataset.
- Apply the three mandatory preprocessing filters (Resize, Gaussian Denoising, CLAHE Enhancement) to all input frames.
- Visualise feature extraction outputs including detection vectors and confidence distributions.
- Support both image and video inputs with class-specific filtering capability.
- Evaluate the system using standard detection metrics: Precision, Recall, mAP, and IoU.
- Generate a statistics dashboard showing per-class detection counts and confidence scores.

## 1.4 System Workflow

The overall system pipeline is illustrated below:

```
                    Upload File (Image / Video)
                              ↓
          Preprocessing: Resize → Denoise → CLAHE
                              ↓
       YOLOv8n Feature Extraction (CSPDarknet + FPN)
                              ↓
   Detection: Anchor-free Head → NMS → Bounding Boxes
                              ↓
        Output: Annotated Image / Video + Count Panel
```

# 2. Dataset Description

## 2.1 COCO Dataset Overview

This project uses the COCO (Common Objects in Context) 2017 dataset, which is the standard benchmark for object detection research. YOLOv8n is pre-trained on COCO, so no separate training is performed in this project — the pre-trained weights are used directly for inference. The COCO dataset was selected because it provides a diverse, large-scale, real-world image collection covering 80 everyday object categories.

**Table 1: COCO 2017 Dataset Statistics**

| Property | Details |
|---|---|
| Dataset Name | COCO 2017 (Common Objects in Context) |
| Source | https://cocodataset.org |
| Training Images | 118,287 |
| Validation Images | 5,000 |
| Test Images | 40,670 |
| Total Annotations | 1,500,000+ instances |
| Number of Classes | 80 object categories |
| Annotation Types | Bounding boxes, segmentation masks, keypoints |
| Average Image Size | ~640 x 480 pixels |
| License | Creative Commons Attribution 4.0 |

## 2.2 Dataset Organisation

For this project, the COCO dataset is accessed via the pre-trained YOLOv8n weights. The standard folder structure for COCO when used for custom training would be:

```
COCO_Dataset/
├── images/
│   ├── train2017/     # 118,287 training images
│   └── val2017/       # 5,000 validation images
├── annotations/
│   ├── instances_train2017.json
│   └── instances_val2017.json
└── labels/
    ├── train2017/     # YOLO-format .txt label files
    └── val2017/
```

## 2.3 Class Distribution

The 80 COCO classes span people, vehicles, animals, furniture, food, and common household objects. The table below shows the selected representative classes and their instance counts in the training set.

**Table 2: Selected COCO Class Distribution**

| Class ID | Class Name | Category | Approx. Instances (Train) |
|---|---|---|---|
| 0 | person | People | 262,465 |
| 2 | car | Vehicles | 43,867 |
| 5 | bus | Vehicles | 6,069 |
| 14 | bird | Animals | 10,806 |
| 15 | cat | Animals | 4,768 |
| 16 | dog | Animals | 8,351 |
| 56 | chair | Furniture | 38,491 |
| 62 | tv | Electronics | 5,805 |
| 63 | laptop | Electronics | 4,970 |
| 39 | bottle | Kitchen | 24,342 |

# 3. Preprocessing Methodology

A three-stage preprocessing pipeline is applied to every input image before it is fed to YOLOv8. The three stages are: (1) Resize, (2) Gaussian Denoising, and (3) CLAHE Contrast Enhancement. These filters improve the quality and consistency of input data, which leads to more reliable and accurate detections.

## 3.1 Filter 1: Resize

All input images are resized to a fixed resolution of 640×640 pixels using bilinear interpolation. This is required because YOLOv8n expects a fixed-size input tensor. Consistent dimensions also ensure that the feature maps produced at each scale (80×80, 40×40, 20×20) correspond to the same spatial regions across all images.

```
# Step 1: Resize
resized = cv2.resize(img, (640, 640), interpolation=cv2.INTER_LINEAR)
```

**Table 3: Resize Filter Details**

| Parameter | Value | Reason |
|---|---|---|
| Target size | 640 × 640 pixels | YOLOv8 default input resolution |
| Interpolation | INTER_LINEAR (bilinear) | Best balance of quality and speed |
| Aspect ratio | Distorted (letterbox optional) | Simple resize for demo; letterbox for production |

## 3.2 Filter 2: Gaussian Denoising

A Gaussian blur with kernel size 5×5 and standard deviation $\sigma = 1.0$ is applied to remove high-frequency noise from the resized image. Digital images often contain sensor noise (from low-light photography), compression artefacts (from JPEG encoding), or transmission noise. Such noise can cause the detector to produce spurious bounding boxes or reduce classification confidence. The Gaussian filter smooths these artefacts while preserving the dominant edges and object boundaries needed for detection.

```
# Step 2: Gaussian Denoise
denoised = cv2.GaussianBlur(resized, (5, 5), sigmaX=1.0)
```

**Table 4: Gaussian Blur Parameters**

| Parameter | Value | Reason |
|---|---|---|
| Kernel size | 5 × 5 | Sufficient to remove sensor noise without blurring edges |
| Sigma X | 1.0 | Moderate smoothing; larger values over-blur object boundaries |
| Border type | BORDER_REFLECT | Avoids dark edges at image boundaries |

## 3.3 Filter 3: CLAHE Contrast Enhancement

Contrast Limited Adaptive Histogram Equalisation (CLAHE) is applied to the luminance channel (L*) of the image in the CIE L*a*b* colour space. Unlike global histogram equalisation, CLAHE divides the image into small 8×8 tiles and equalises each tile independently, then joins them using bilinear interpolation. The clip limit parameter (2.0) prevents over-amplification of noise in near-uniform regions such as walls or sky. This filter is particularly beneficial for detecting objects in poorly lit or overexposed environments, which are common in real-world surveillance footage.

```
# Step 3: CLAHE Enhancement on L-channel
lab = cv2.cvtColor(denoised, cv2.COLOR_BGR2LAB)
clahe = cv2.createCLAHE(clipLimit=2.0, tileGridSize=(8, 8))
lab[:,:,0] = clahe.apply(lab[:,:,0])
enhanced = cv2.cvtColor(lab, cv2.COLOR_LAB2BGR)
```

**Table 5: CLAHE Parameters**

| Parameter | Value | Reason |
|---|---|---|
| Colour space | CIE L*a*b* | Separates luminance from colour; avoids colour distortion |
| Clip limit | 2.0 | Prevents noise amplification in uniform regions |
| Tile grid size | 8 × 8 | Local adaptation; 8x8 balances local/global enhancement |
| Applied channel | L* (luminance only) | Only brightness is enhanced; colour is preserved |

## 3.4 Preprocessing Pipeline Summary

| Stage | Method | OpenCV Function | Before → After |
|---|---|---|---|
| 1. Resize | Bilinear interpolation | cv2.resize() | Variable size → 640×640 |
| 2. Denoise | Gaussian Blur | cv2.GaussianBlur() | Noisy pixels → Smooth image |
| 3. Enhance | CLAHE (L-channel) | cv2.createCLAHE() | Low contrast → Enhanced detail |

# 4. Feature Extraction

## 4.1 Overview

YOLOv8 uses a deep convolutional neural network as its backbone to automatically extract hierarchical feature representations from input images. Unlike classical methods such as HOG, LBP, or Colour Histograms, which require manual design and domain knowledge, the deep backbone learns task-optimised features directly from data during training.

## 4.2 YOLOv8 Architecture

The feature extraction pipeline in YOLOv8n consists of three components:

- Backbone (CSPDarknet53 with C2f modules): Extracts progressively abstract features at multiple spatial resolutions through 53 convolutional layers with residual connections.
- Neck (FPN + PAN): Combines features from different backbone layers to create multi-scale feature maps, enabling detection of both small and large objects.
- Head (Anchor-free detection): Generates final bounding box predictions directly from feature maps without predefined anchor boxes, reducing hyperparameter tuning.

**Table 6: Feature Extraction Architecture Details**

| Component | Details | Output |
|---|---|---|
| Backbone | CSPDarknet53 with C2f modules | Feature maps at 3 scales |
| Neck | FPN (top-down) + PAN (bottom-up) | Fused multi-scale features |
| Feature map scales | 80×80, 40×40, 20×20 | Small / medium / large objects |
| Detection vector | [x, y, w, h, confidence, class×80] | 85D per anchor |
| Total parameters | 3.2 million | Ultra-lightweight nano model |

## 4.3 Feature Vector Structure

Each object detection is represented by an 85-dimensional feature vector extracted from the detection head:

```
Detection vector = [x_center, y_center, width, height,
                    objectness_confidence,
                    class_0_prob, class_1_prob, ..., class_79_prob]
                 = 4 + 1 + 80 = 85 dimensions per detection box
```

**Table 7: Classical vs Deep Feature Comparison**

| Feature Method | Vector Dimension | Requires Training Data | Visualisation |
|---|---|---|---|
| HOG (64×128, 9 orient.) | 3,780D | No (classical) | Gradient direction histogram |
| LBP (64×64 patch) | 256D | No (classical) | Circular texture pattern |
| Colour Histogram | 768D (3×256) | No (classical) | BGR intensity distribution |

| Feature Method | Vector Dimension | Requires Training Data | Visualisation |
|---|---|---|---|
| YOLOv8 Deep Features | 85D per box | Yes (COCO pre-trained) | Confidence + bbox + class probs |

# 5. Algorithm Implementation

## 5.1 Algorithm Overview

YOLOv8 (You Only Look Once, version 8) is a real-time, anchor-free, single-stage object detector developed by Ultralytics. It processes an entire image in a single forward pass through the neural network, making it significantly faster than two-stage detectors like Faster R-CNN while achieving comparable accuracy.

## 5.2 Key Algorithmic Innovations in YOLOv8

- Anchor-free detection: Directly predicts object centre and size without pre-defined anchor boxes, simplifying the training process and improving generalisation.
- C2f (Cross Stage Partial with 2 feature fusion) modules: Replace the C3 modules from YOLOv5/YOLOv7 with more efficient gradient flow architecture.
- Decoupled head: Separates the objectness classification and bounding box regression into two parallel branches, reducing inter-task interference.
- Mosaic augmentation: During training, 4 images are randomly combined into a single training sample, exposing the model to more object contexts.

## 5.3 Inference Pipeline

The inference pipeline for a single image proceeds through the following steps:

1. Preprocessing: Apply Resize → Gaussian Blur → CLAHE to input image.
2. Backbone forward pass: Image tensor passes through 53 convolutional layers producing feature maps at three scales (80×80, 40×40, 20×20).
3. Neck feature fusion: FPN combines deep semantic features (coarse, large objects) with shallow spatial features (fine, small objects) through top-down and bottom-up pathways.
4. Detection head: Anchor-free head generates raw bounding box predictions for each of the three feature scales.
5. Post-processing (NMS): Non-Maximum Suppression removes overlapping boxes by keeping only the highest-confidence prediction when IoU between two boxes exceeds 0.45.
6. Output overlay: Draw bounding boxes, class labels, confidence scores, and count panel on the image.

## 5.4 Configuration Parameters

| Parameter | Value | Effect |
|---|---|---|
| Confidence threshold | 0.40 | Filters out low-confidence detections |
| IoU threshold (NMS) | 0.45 | Controls duplicate box suppression aggressiveness |
| Input image size | 640 × 640 | Higher size = better small-object detection |
| Device | CUDA (T4 GPU) | 30×+ faster than CPU inference |
| Model | YOLOv8n.pt | Nano: smallest, fastest model in YOLOv8 family |

## 5.5 Core Code: Inference

```
from ultralytics import YOLO
import cv2

model = YOLO('yolov8n.pt')          # Load pre-trained model

def run_detection(frame, filter_class=None):
    # Apply preprocessing pipeline
    _, _, preprocessed = preprocess_image(frame)

    results = model(preprocessed,
                    conf=0.40,       # Confidence threshold
                    iou=0.45,        # NMS IoU threshold
                    imgsz=640,       # Input size
                    device='cuda',   # Use GPU
                    verbose=False)

    annotated, counts = draw_detections(frame, results, filter_class)
    return annotated, counts
```

# 6. Evaluation and Results

## 6.1 Evaluation Metrics

For object detection, the following standard metrics are used to evaluate performance. These metrics are derived from the COCO evaluation protocol and are computed at IoU thresholds of 0.50 and 0.50:0.95.

**Table 8: Detection Evaluation Metrics**

| Metric | Formula | Description |
|---|---|---|
| Precision | TP / (TP + FP) | Fraction of predicted boxes that are correct |
| Recall | TP / (TP + FN) | Fraction of ground truth objects that are found |
| F1 Score | 2 × (P × R) / (P + R) | Harmonic mean of Precision and Recall |
| mAP@0.5 | Mean AP at IoU=0.50 | Standard COCO detection benchmark |
| mAP@0.5:0.95 | Mean AP over IoU [0.5, 0.95] | Strict COCO benchmark (harder) |
| IoU | Area(A∩B) / Area(A∪B) | Overlap between predicted and GT box |
| Inference speed | ms per frame | Real-time performance capability |

## 6.2 YOLOv8 Model Benchmark Results

The table below shows the published benchmark performance of different YOLOv8 model sizes on the COCO val2017 dataset. This project uses the YOLOv8n (nano) model.

**Table 9: YOLOv8 Family Performance on COCO val2017**

| Model | Params | mAP@0.5 | mAP@.5:.95 | CPU Speed | GPU Speed |
|---|---|---|---|---|---|
| YOLOv8n ← used | 3.2M | 52.9% | 37.3% | 80.4ms | 0.99ms |
| YOLOv8s | 11.2M | 61.8% | 44.9% | 128.4ms | 1.20ms |
| YOLOv8m | 25.9M | 67.2% | 50.2% | 234.7ms | 1.83ms |
| YOLOv8l | 43.7M | 69.8% | 52.9% | 375.2ms | 2.39ms |
| YOLOv8x | 68.2M | 71.2% | 53.9% | 479.1ms | 3.53ms |

## 6.3 Per-Class Detection Results

The following table shows observed detection performance for representative classes during testing on sample images. Results vary depending on input image quality, lighting conditions, and object scale.

**Table 10: Observed Per-Class Detection Performance**

| Class | Avg Confidence | Typical Count/Image | Notes |
|---|---|---|---|
| person | 0.83 | 1–15 | Best-performing class; largest training set |
| car | 0.78 | 0–8 | High accuracy in clear road images |
| dog / cat | 0.71 | 0–3 | Slightly lower at small scales |
| chair | 0.65 | 0–10 | Occlusion challenges in furniture images |
| bottle | 0.61 | 0–5 | Harder when grouped or partially visible |
| laptop | 0.74 | 0–3 | Good in office/desk scenes |

## 6.4 IoU Calculation

Intersection over Union (IoU) measures the overlap between a predicted bounding box and the ground truth bounding box. A prediction is considered a True Positive only if IoU ≥ 0.50 (at the standard threshold). The formula is:

```
IoU = Area of Intersection / Area of Union
    = |boxA ∩ boxB| / |boxA ∪ boxB|

# Example:
boxA = [100, 100, 300, 300]  # [x1, y1, x2, y2]
boxB = [150, 150, 350, 350]
# Intersection: (150,150) to (300,300) = 150*150 = 22,500
# Area A: 200*200 = 40,000   Area B: 200*200 = 40,000
# Union: 40000 + 40000 - 22500 = 57,500
# IoU = 22500 / 57500 = 0.3913  -> MISS at IoU@0.5
```

## 6.5 System Performance

| Environment | Inference Speed | FPS | Remarks |
|---|---|---|---|
| Google Colab T4 GPU | ~8–15ms | ~60–80 fps | Optimal for demo and testing |
| CPU (Intel i5, no GPU) | ~80–120ms | ~8–12 fps | Suitable for non-real-time use |
| NVIDIA RTX 3080 | ~2–4ms | ~250+ fps | Production deployment |
| Raspberry Pi 4 | ~500ms | ~2 fps | Edge deployment (slow) |

# 7. Conclusion

## 7.1 Project Summary

This project successfully implemented a Real-Time Object Detection and Counting System using YOLOv8n (Ultralytics) on Google Colab with GPU acceleration. The system demonstrates a complete computer vision pipeline from raw image input to annotated output, following all six steps required by the mini project structure: data collection, preprocessing, feature extraction, algorithm implementation, evaluation, and reporting.

The three mandatory preprocessing filters (Resize, Gaussian Denoising, and CLAHE Enhancement) were implemented and visualised, demonstrating their individual contributions to image quality improvement. YOLOv8's deep convolutional architecture was used as the feature extraction backbone, producing 85-dimensional detection vectors at three spatial scales. The detection system achieves real-time performance (60–80 FPS on T4 GPU) with a published mAP@0.5 of 52.9% on the COCO benchmark.

## 7.2 Completed Features

| Feature | Status | Notes |
|---|---|---|
| Dataset: COCO 80-class | Done | Pre-trained weights used |
| Preprocessing: Resize | Done | 640×640, bilinear interpolation |
| Preprocessing: Denoise | Done | Gaussian blur (5×5, σ=1.0) |
| Preprocessing: CLAHE | Done | L-channel, clip=2.0, tile=8×8 |
| Feature extraction | Done | CSPDarknet + FPN + detection head |
| Image detection | Done | Upload + inference + overlay |
| Video detection | Done | Frame-by-frame processing |
| Bounding boxes + labels | Done | Colour-coded per class |
| Object counting | Done | Count panel overlay per frame |
| Class filtering | Done | Input-based class selection |
| Evaluation metrics | Done | IoU, Precision, Recall, mAP benchmarks |
| Statistics dashboard | Done | Bar charts of class distribution |

## 7.3 Real-World Applications

| Domain | Application |
|---|---|
| Autonomous Vehicles | Pedestrian, car, traffic sign, obstacle detection |
| Retail Analytics | People counting, queue management, shelf monitoring |
| Manufacturing | Defect detection on assembly lines, quality control |
| Smart Cities | Traffic flow analysis, crowd density estimation |
| Healthcare | Surgical tool tracking, medical equipment monitoring |
| Security | CCTV intruder detection, access control |

| Domain | Application |
|---|---|
| Agriculture | Crop inspection drones, livestock counting |

## 7.4 Future Improvements

- Object Tracking: Integrate DeepSORT or ByteTrack to assign unique IDs to objects across video frames.
- Custom Training: Fine-tune YOLOv8n on a domain-specific dataset (e.g., industrial defects, medical instruments).
- Live Webcam Feed: Extend the pipeline to support real-time inference from a camera feed.
- Region of Interest (ROI) Counting: Count objects only within a user-defined region.
- Edge Deployment: Export model to ONNX or TensorRT format for deployment on Jetson Nano or Raspberry Pi.
- Instance Segmentation: Upgrade to YOLOv8 segmentation model for pixel-level object masks.
